54 **A method for the manufacture of a material in the form of sheets or a web provided with a watermarklike pattern.**

57 A material (1) in the form of sheets or a web is provided with a watermarklike pattern (12) in the form of a text, figure or similar identification mark visible or displayable in transmitted light by means of relieflike mechanical working off of material, for example grinding, milling etc., corresponding to the desired pattern (12).

**EP 0 195 887 A2**

A METHOD FOR THE MANUFACTURE OF A MATERIAL IN THE FORM OF SHEETS  
OR A WEB PROVIDED WITH A WATERMARKLIKE PATTERN

5       The present invention relates to a method for the manufacture  
of a material in the form of sheets or a web, in particular  
writing or document paper such as securities of the type of cheques,  
bank-notes etc., provided with marks detectable or made visible in  
transmitted light or radiation. The invention also relates to  
material in the form of sheets or a web manufactured in accordance  
10       with the method.

      The providing of writing and document paper with so-called  
watermarks has been known for a long time. Such watermarks in  
principle are invisible but appear clearly when the sheet of  
paper provided with watermark is held up against the light or  
15       light is transmitted through it in some other manner. Tradition-  
ally watermarks are produced by impressions in, or contact with,  
the strongly hydrated paper pulp distributed on the screen of  
the paper machine. The said operation is carried out with the  
help of a so-called dandy roll.

20       Such watermarks are expensive to produce if the watermarked  
material is not to be manufactured in large quantities, and it  
will not be economically justifiable as a rule therefore to  
provide private note-paper with special watermarks.

      However, there is a possibility of producing so-called false  
25       watermarks (marks of watermark character detectable or made  
visible in transmitted light or radiation) in a chemical manner.  
These "watermarks" are produced in that the optical refractive  
index of the paper is altered locally by applying a chemical  
substance, for example a polymerizable substance, to the paper  
30       in the desired pattern. However, it has been found that these  
false watermarks are often well visible without any transmittance  
of light and that they give the impression of a "grease mark"  
having been made on the paper.

      The abovementioned methods are subject to disadvantages  
35       which can be avoided with the help of the present invention  
which is characterized in that desirable watermarklike markings

are produced by means of differentiated working off of material from the material in the form of sheets or a web to provide a graded reduction of thickness to forming of a text or a picture.

5 The invention will be described in the following with the help of the attached schematic drawing wherein Fig. 1 shows how, for example, a paper web can be provided with a watermarklike pattern by the method in accordance with the present invention and Fig. 2 illustrates in strong enlargement the area surrounded by broken lines in Fig. 1.

10 A marking of the watermark type not directly visible has been used for a long time as a proof of legitimacy for documents and securities of the type of bank-notes, share-certificates etc. but marking of this type has also been used to identify the manufacturer of a paper, on business note-paper and to a certain  
15 limited extent for private note-paper, mainly hand-made paper. The reason why the marking of machine-manufactured private note-paper with watermarks is economically not justifiable is that with present methods it is hardly worthwhile to manufacture less than approx. ten tons of paper with the same marking.

20 By means of the method in accordance with the present invention, it is possible, however, to produce in an economic manner private note-paper, business paper and document paper in substantially smaller quantities than if traditional watermarking were to be used. It is a further advantage that the marking can  
25 be placed on the individual paper sheets with considerably greater precision and that the contours of the marking will be more distinct.

In Fig. 1 is shown how a paper web 1 is provided with watermarklike pattern. The paper web is fed over deflection  
30 rollers 2 and 3 and a matrix roll 4. The matrix roll 4 has local projections (matrices) 5 which rest against the regions of the web which are to be provided with the said pattern. As indicated in Fig. 1 the matrix roll 4 rotates in the direction of the paper web at the same speed as the latter so that any  
35 slipping between the roll 4 and the web 1 is avoided. Adjoining the roll 4 a grinding roller 6 is arranged at such an adjustable

- 3 -

distance from the roll 4 that parts of the paper web 1 which rest against the surface of the roll can narrowly pass the gap between the grinding roller 6 and the roll 4. This obviously means that no grinding occurs on these parts of the web 1. Fig. 1 further shows that the grinding roller 6 is smaller than the roll 4 and that it is adapted to rotate in the direction towards the roll 4. The grinding roller 6 is rotated at a speed which is higher, preferably substantially higher, than the speed of rotation of the roll 4.

Fig. 2 illustrates in greater detail how the local projections 5 on the material roll 4 can be constituted of mutually adjoining or interconnecting portions 7-11 with points located at different heights above the surface of the roll 4 thus forming a relieflike surface structure which corresponds to the desired pattern. When the part of the matrix roll 4 which carries such a projection 5 passes along the grinding roll 6 the paper web 1 will be raised towards the grinding roll 6, the part so raised being ground away in a graded manner. Thus in the web 1 a "grinding image" (partly appearing at 12) is obtained which in shape, height and position substantially corresponds to the projections 5. On inspecting this grinding image in transmitted light a watermarklike pattern of mutually adjoining or interconnecting portions of varying degree of light transmittance will be visible on the paper web 1.

The local projections 5 can be produced, for example, from any suitable lasting material such as steel.

CLAIMS

1. A method for the manufacture of a material (1) in the form of sheets or a web provided with a watermarklike pattern (12)  
5 of mutually adjoining or interconnecting portions of different thickness and degree of transmittance, c h a r a c t e r i z e d i n t h a t the said pattern is produced by the graded working off of material within respective portions.
2. A method in accordance with claim 1, c h a r a c t e r i z e d  
10 i n t h a t the working off of material is achieved by grinding, milling or similar cutting operation.
3. A method in accordance with claim 1 or 2, c h a r a c t e r -  
i z e d i n t h a t one side of the sheet or web (1) is adapted to be pressed with a relieflike matrix (5) corresponding  
15 to the said pattern (12) against a rapidly rotating grinding or cutting roller (6), whereby the said working off of material is carried out along the parts so pressed against said roller (6).
4. A method in accordance with claim 3 for the manufacture of sheets provided with the said pattern cut off or torn off a movable  
20 paper web (1), c h a r a c t e r i z e d i n t h a t the paper web (1) is fed through the gap between the grinding roller (6) and a roll (4) arranged adjoining the same which on its surface carries the said matrix (5) and which is adapted to rotate in the direction of feed of the paper web, the smallest distance between  
25 the grinding roller (6) and the surface of the roll (4) being at least of equal size as the thickness of the paper web (1), whilst the shortest distance between the grinding roller (6) and the highest point of the relieflike matrix surface in relation to the surface of the roll is greater than zero so that grinding holes  
30 right through the paper web are avoided.
5. A method in accordance with claim 4, c h a r a c t e r i z e d i n t h a t the grinding roller (6) (at the said gap) is rotated in the direction towards the direction of feed of the paper web and at a higher, preferably much higher, speed than the  
35 said roll (4).

6. A method in accordance with claim 4 or 5, characterized in that the periphery speed of the roll corresponds to the speed of feed of the paper web.
7. A writing or document paper comprising a watermarklike pattern
- 5 (12) of adjoining or interconnecting regions of different degree of thickness and light transmittance characterized in that the said pattern is produced by the graded working off of material within respective portions.
